Name that Approach

For each scenario, decide whether it's supervised, unsupervised, or reinforcement learning. For supervised, also say whether it's classification or regression.

1. A program learns to play chess by playing millions of games against itself, with only win, loss, or draw as feedback.

2. A real estate site predicts a home's sale price from its square footage, location, and number of bedrooms.

3. An email filter learns from thousands of messages users have marked as "spam" or "not spam."

4. A cybersecurity team looks for unusual network traffic patterns, with no examples of past attacks to learn from.

5. A hospital uses past patient records, each marked "readmitted" or "not readmitted," to flag high-risk patients at discharge.

6. A weather service predicts tomorrow's high temperature from decades of historical readings.

7. A streaming service groups its users by viewing habits without any predefined categories.

8. A traffic light system adjusts its signal timing and is rewarded when average wait times go down.
